Kurzfassung

Erstellung einer Echtzeit-Robotersteuerungsplattform unter Verwendung von Salamander OS, Xenomai, QEMU und PCV-521 in der Yocto-Umgebung. Die Plattform basiert auf Salamander OS und nutzt Xenomai für Echtzeit- Funktionen. Dazu muss im ersten Schritt die Virtualisierungsplattform evaluiert werden. (QEMU, Hyper-V, Virtual Box, etc.) Als weiterer Schritt folgt die Anbindung eines Roboters über eine VARAN-Bus Schnittstelle. Das gesamte System wird in der Yocto-Umgebung erstellt und konfiguriert. Das Hauptziel der Arbeit ist es, herauszufinden, wie die Integration von Echtzeit-Funktionen und effizienten Kommunikationssystemen in eine Robotersteuerungsplattform die Reaktionszeit und Zuverlässigkeit von Roboteranwendungen verbessern kann

1 Introduction

In today's industrial production and automation, robot systems are well established and of crucial importance. Robots must react to their environment and perform time-critical tasks within strict time constraints. Delays or errors can have catastrophic consequences in some cases. Traditional operating systems, such as Windows or Linux, are often not suitable for these types of real-time requirements as they cannot guarantee deterministic execution times. Therefore, real-time operating systems are required that are specifically designed to react to events within fixed time limits and prioritise the execution of high-priority processes.

The core component of an RTOS that enables real-time capabilities is the kernel. The kernel is responsible for managing system resources, scheduling tasks, and ensuring deterministic behavior. It employs preemptive scheduling mechanisms to allow high-priority tasks to preempt lower-priority tasks, ensuring that time-critical tasks are not delayed. The kernel also implements priority-based scheduling algorithms, such as Rate Monotonic Scheduling (RMS) or Earliest Deadline First (EDF), to schedule tasks based on their priorities and timing constraints. Additionally, RTOS kernels are designed to minimize interrupt latency, which is crucial for real-time applications that require immediate response to external events.

In these RTOS systems, task scheduling is based on so-called priority-based preemptive scheduling. Each task in a software application is assigned a priority. A higher priority means that a faster response is required. Preemptive task scheduling ensures a very fast response. Preemptive means that the scheduler can stop a currently running task at any point if it recognizes that another task needs to be executed immediately. The basic rule on which priority-based preemptive scheduling is based is that the task with the highest priority that is ready to run is always the task that must be executed. So if both a task with a lower priority and a task with a higher priority are ready to run, the scheduler ensures that the task with the higher priority runs first. The lower priority task is only executed once the higher priority task has been processed. Real-time systems are usually categorized as either soft or hard real-time systems. The difference lies exclusively in the consequences of a violation of the time limits.

Hard real-time is when the system stops operating if a deadline is missed, which can have catastrophic consequences. Soft real-time exists when a system continues to function even if it cannot perform the tasks within a specified time. If the system has missed the deadline, this has no critical consequences. The system continues to run, although it does so with undesirably lower output quality.

1.1 Application Context

This master's thesis was written at SIGMATEK GmbH & Co KG [1]. This section provides necessary information about the starting point and boundary conditions of the thesis, as the work should be reproducible with the means used.

SIGMATEK uses its own customized Linux distribution to be run on their self-manufactured CPUs, namely Salamander 4. This operating system

, to employ hard real-time in their Salamander4 is virtualized through third party services.

The details of this operating system are explained in section 3

1.2 State of the art

1.3 Problem and task definition

In robotics, accurate and timely control is crucial to ensure precise movements and reliable interaction with the environment. However, existing robot control systems often have limitations in terms of real-time capabilities and communication efficiency, which can have a detrimental effect on response time and reliability. The challenge is to develop a powerful real-time robot control platform that overcomes these limitations and improves the performance of robotic applications.

1.4 Objective

The main objective of this work is to create a real-time robot control platform that integrates Salamander OS, Xenomai, QEMU and PCV-521 in the Yocto environment.

This integration is expected to lead to a significant improvement in the response time and reliability of robot applications.

2 Methodology

In diesem Abschnitt werden sämtliche theoretischen Konzepte und Randbedingungen sowie praktische Methoden, die zur Erreichung der Zielsetzung dieser Masterarbeit beigetragen haben, detailliert beschrieben.

Zu Beginn der Arbeit wurde eine ausführliche Analyse der einzelnen Virtualisierungsmöglichkeiten von Salamander 4 durchgeführt. Im Besonderen wurde hier die Virtualisierungsperformance von Ubuntu 22.04, Windows 10 und WSL unter QEMU verglichen.

First, a comprehensive literature review is conducted to understand the current trends and challenges in real-time robot control. Based on the literature study, a suitable virtualisation platform is selected.

After the selection of the virtualisation platform, the robot control platform is implemented. This step includes the installation and configuration of Salamander OS, Xenomai, QEMU and PCV-521 in the Yocto environment. Once the platform has been implemented, the robot is connected via a VARAN bus interface. Finally, the platform is evaluated to determine how the integration of real-time functions and efficient communication systems improves the response time and reliability of robot applications.

- Evaluation der Virtualisierungsplattform: Ich werde verschiedene Virtualisierungsplattformen wie QEMU, Hyper-V, Virtual Box usw. evaluieren. Dies ist ein wichtiger Schritt, um die beste Plattform für meine Anforderungen zu finden.

- Erstellung und Konfiguration des Systems in der Yocto-Umgebung: Ich werde das Yocto-Framework verwenden, um mein Embedded Linux System zu erstellen und zu konfigurieren. Yocto bietet viele Tools und Funktionen, die mir bei der Erstellung und Konfiguration meines Systems helfen können.

- Anbindung eines Roboters über eine VARAN-Bus Schnittstelle: Ich plane, einen Roboter in mein System zu integrieren. Ich werde eine VARAN-Bus Schnittstelle verwenden, um eine schnelle und zuverlässige Kommunikation zwischen dem Roboter und dem Steuerungssystem zu gewährleisten.

Trace-cmd was used for tracing the Linux kernel. It can record various kernel events such as interrupts, scheduler decisions, file system activity, function calls in real time. Trace-cmd helped in getting detailed insights into system behaviour and identify reasons for latency [2].

The data that was recorded by trace-cmd was then fed into Kernelshark, which is a graphical front-end tool [3]. It visualizes the recorded kernel trace data in a readable way on an interactive timeline, which facilitated the process of identifying patterns and correlations between events.

By further filtering the displayed events according to specific criteria such as processes, event types or time ranges, the latency issues were analyzed.

Real-time operating system capabilities were provided by Xenomai, which is real-time development framework that extends the Linux kernel. It enables low-latency and deterministic execution of time-critical tasks. Xenomai introduces a dual-kernel approach with a real-time kernel coexisting alongside Linux. A key utility within the Xenomai suite is the latency tool, which benchmarks the timer latency - the time it takes for the kernel to respond to timer interrupts or task activations. The tool creates real-time tasks or interrupt handlers and measures the latency between expected and actual execution times [4].

3 Salamander Operating System

Salamander 4 is the proprietary operating system of SIGMATEK. It is based on Linux version 5.15.94 and integrates Xenomai 3.2, a real-time development environment [4]. Salamander 4 is a 64-bit system, which refers to the x86_64 architecture. The real-time behaviour is achieved through the use of Symmetric Multi-Processing (SMP) and Preemptive Scheduling (PREEMPT). In addition, it utilises IRQPIPE to process interrupts in a way that meets the real-time requirements of the system. The output of the command `uname -a` can be observed in code 1.

```
1 root@sigmatek-core2:~# uname -a
2 Linux sigmatek-core2 5.15.94 #1 SMP PREEMPT IRQPIPE Tue Feb 14 18:18:05 UTC
   2023 x86_64 GNU/Linux
```

Code 1: System information

Xenomai consists of 3 parts. These can be found in the Table 1.

Table 1: Xenomai architecture

Teil	Beschreibung
i-pipe	Kernelerweiterung für das Domain-Konzept
Xenomai Kernel	Benutzt die i-pipe, und hängt sich als root-Domain ein
Xenomai User	Programme (LRT) verwenden diese Bibliothek, um Xenomai Funktionen verwenden zu können.

Xenomai beruht auf einem Domain-Konzept, das bedeutet, dass alle IRQ an die erste Domain gesendet werden. (root – Domain / Xenomai) Nur wenn diese nichts mehr zu tun hat, dann darf die 2. Domain arbeiten. Das bedeutet, erst wenn alle Xenomai Task in einem Wartezustand sind, arbeiten die Linux-Tasks.

In der Regel unterbricht der Prozessor beim IRQ-Handling seine aktuellen Aktivitäten, um einen Interrupt zu bearbeiten, während die IRQ-Behandlung von Xenomai einen Interrupt-Pipeline-Mechanismus verwendet, der das gleichzeitige Abrufen und Vorbereiten eines anderen Interrupts ermöglicht, während ein Interrupt bearbeitet wird, was die Leistung verbessert und die Latenzzeit verringert.

Was Xenomai4 von seinem Vorgänger Xenomai3 unterscheidet, ist die vollständige Neugestaltung der Ausführungsphase mit hoher Priorität. Dies geschah aus Gründen der Portabilität und

Wartungsfreundlichkeit: I-pipe - die zweite Iteration der ursprünglichen Adeos-Interrupt-Pipeline
- wurde vollständig durch Dovetail ersetzt.

Table 2: Domain specific functions

Xenomai spezifische Funktionen	Linux spezifische Funktionen
Tasks	Dateizugriffe
Mutexes, Semaphoren, Events	Netzwerk

Ein Aufruf dieser Funktionen erfordert die entsprechende Domain. Wenn der Task in der falschen Domain läuft, dann wird ein Domain-Wechsel forciert. Ein Domainwechsel von Xenomai nach Linux geht relativ einfach. Aber der Wechsel von Linux nach Xenomai braucht Unterstützung, und dafür ist die Hilfe des Gatekeepers notwendig. Das bedeutet, der Gatekeeper hilft einem Task von Linux nach Xenomai zu wechseln.

3.1 Task priorities

Es gibt grundsätzlich 4 Gruppen

Table 3: Overview of the priority groups and their relationships

Prioritätsgruppe	Bereich
Xenomai Priorität	0 bis 99
Linux RT Priorität	1 bis 99
Linux (Nice Level) Priorität	-20 bis 19
RTK Priorität	0 bis 14

3.2 Memory Management

Es gibt verschiedene Speicherbereiche

Linux/System/Programm Speicher Der Speicher, den Linux und Programme belegt haben. Dieser Speicher ist intern in viele Teile aufgeteilt. (DMA, ...)

LRT-Heap Speicher Speicher den der LRT verwendet, oder welcher über ein CIL Funktionen angefordert wird.

App Heap, App Code, ...

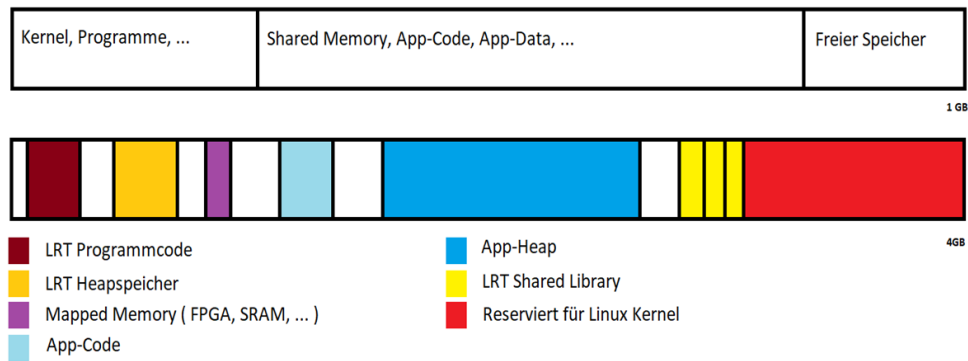

Figure 1: Memory Management

Eine LASAL CPU besteht aus den folgenden Software-Modulen:

- Operating system
- Loader
- Hardware-Klassen

Die Schnittstelle zwischen den einzelnen Modulen wird in Abbildung 2 durch einen Pfeil gekennzeichnet.

Figure 2: LASAL CPU

4 Comparison of Real-Time Latency

In the initial phase, a comparative latency analysis was conducted between the hardware version and the virtualized version of Salamander 4. For this purpose, the latency tool of the Xenomai test suite was used. The latency was measured under two conditions, idle and CPU-stressed. The goal was to optimize the latency of the virtualisation of Salamander 4 OS to closely match that of the bare metal version.

Vorgehensweise von [5]

Table 4: Kernel and Patches

Kernel	Patches
.	.
.	.

After analyzing the initial latency of both versions, Trace-cmd and Kernelshark were used to further inspect the reasons that caused this divergence.

4.1 Salamander 4 Bare Metal

Salamander 4 Bare Metal refers to the proprietary hardware of SIGMATEK used to employ the custom operating system, including

Figure 3 shows latency of hardware Salamander4.

Figure 3: Latency hardware

4.2 Salamander 4 Virtualisation

In addition to providing Salamander 4 on its own hardware, SIGMATEK has also developed a virtualised version of this operating system. It was developed using Yocto, an open source project that allows customised Linux distributions to be created for embedded systems [6]. The virtualisation runs in a QEMU environment, which is an open source tool for hardware virtualisation [7]. With the help of the script depicted in code 3, Salamander 4 is started together with the necessary hardware components in the QEMU environment. This makes it possible to run Salamander 4 on a variety of host systems, regardless of the specific hardware of the host. Upon generating the necessary files, Yocto generates a QEMU folder with the following components shown in code 2.

```
1  sigma_ibo@localhost:~/Desktop/salamander-image$ ls -l
2  bzImage
3  drive-c
4  ovmf.code.qcow2
5  qemu_def_bkp.sh
6  qemu_def.sh
7  salamander-image-sigmatek-core2.ext4
8  stek-drive-c-image-sigmatek-core2.tar.gz
9  vmlinux
```

Code 2: Contents of QEMU folder for Salamander 4

```

1  #!/bin/sh
2
3  if [ ! -d drive-c/ ]; then
4      echo "Filling drive-c/"
5      mkdir drive-c/
6      tar -C drive-c/ -xf stek-drive-c-image-sigmatek-core2.tar.gz
7  fi
8
9  exec qemu-system-x86_64 -M pc,accel=kvm -kernel ./bzImage \
10 -m 2048 -drive
      file=salamander-image-sigmatek-core2.ext4,format=raw,media=disk \
11 -append "console=ttyS0 console=tty1 root=/dev/sda rw panic=1
      sigmatek_lrt.QEMU=1 ip=dhcp rootfstype=ext4 schedstats=enable" \
12 -net nic,model=e1000,netdev=e1000 -netdev bridge,id=e1000,br=nm-bridge \
13 -fsdev local,security_model=none,id=fsdev0,path=drive-c -device
      virtio-9p-pci,id=fs0,fsdev=fsdev0,mount_tag=/mnt/drive-C \
14 -device vhost-vsock-pci,guest-cid=3,id=vsock0 \
15 -drive if=pflash,format=qcow2,file=ovmf.code.qcow2 \
16 -no-reboot -nographic

```

Code 3: QEMU script for starting Salamander 4 virtualisation

Here is a description of the used components:

- **bzImage**: Compressed Linux kernel image, loaded by QEMU at system start.
- **ovmf.code.qcow2**: Firmware file for QEMU, enables UEFI boot process.
- **qemu_def.sh**: Shell script, starts QEMU with correct parameters to boot Salamander 4 OS.
- **stek-drive-c-image-sigmatek-core2.tar.gz**: Archive containing files for C drive, unpacked and copied to drive-c/ directory by qemu_def.sh script.
- **drive-c**: Directory, serves as C drive for QEMU system, created and filled by qemu_def.sh script..
- **salamander-image-sigmatek-core2.ext4**: Root file system for Salamander 4 OS, used as hard drive for QEMU system.
- **vmlinux**: Uncompressed Linux kernel image, typically used for debugging, contains debugging symbols not present in bzImage.

When the script is started from the host, the QEMU process can be scheduled to run on any available core, as it is noted bound to a specific CPU core. This means that the QEMU process may frequently switch between different cores, leading to an increase in latency. As the goal was to reduce latency in the guest, the first step was to isolate a CPU of the host and dedicate it solely to the QEMU process, so that it cannot be used for other tasks on user level. However, the `isolcpus` function only isolates at the user level and does not affect kernel tasks. Consequently, these kernel tasks and interrupts can still utilize the CPU.

Figure 4 shows latency of QEMU default Salamander4.

Figure 4: Latency no taskset

Figure 5 shows latency of QEMU taskset Salamander4.

Figure 5: Latency taskset

Upon isolating a CPU to the QEMU process, it was anticipated that the guest would utilize nearly 100% of the CPU's capacity, with minimal to no intervention from the host. However, the `isolcpus` function only isolates at the user level and does not affect kernel tasks. Consequently, these kernel tasks and interrupts can still utilize the CPU. This led to the investigation of the causes for the observed high and inconsistent latency. The guest operates within the `kvm_entry` and `kvm_exit` events of the host. Kernelshark revealed a high frequency of `kvm_exit` events, indicating that the guest frequently relinquishes control of the CPU back to the host. This frequent switching hinders the guest's ability to run continuously, thereby increasing the virtualization latency. To further understand this, `trace-cmd` was employed to trace various events in the host-guest communication, including the reasons for these events. Specifically, the causes for `kvm_exit` events were analyzed. The command `sudo trace-cmd record -e all -A @3:823 -name Salamander4 -e all` was executed on the host for a duration of 5 seconds. The results in Figure 6 were obtained. Additionally, table 5 provides a short description of the observed `kvm_exit` events.

Exit Reason	Description
APIC_WRITE	Triggered when the guest writes to its APIC.
EXTERNAL_INTERRUPT	Triggered by external hardware interrupts.
HLT	Triggered when the guest executes the HLT instruction.
EPT_MISCONFIG	Triggered by a misconfiguration in the EPT.
PREEMPTION_TIMER	Triggered when the host's preemption timer expires.
PAUSE_INSTRUCTION	Triggered when the PAUSE instruction is executed.
EPT_VIOLATION	Triggered by a violation of the EPT permission settings.
IO_INSTRUCTION	Triggered when the guest executes an I/O instruction.
EOI_INDUCED	Triggered when an EOI signal is sent to the APIC.
MSR_READ	Triggered when the guest reads from a MSR.
CPUID	Triggered when the guest executes the CPUID instruction.

Table 5: Description of `kvm_exit` reasons

Figure 7 shows `kvm_exit` frequency with CPU isolation.

Figure 6: kvm exits

Figure 7 shows `kvm_exit` frequency without CPU isolation.

Figure 7: kvm exits default

Without CPU isolation, context switches take place at operating system level and not at hypervisor level. This explains why there are fewer `kvm_exit` events. However, this will also, as previously shown, lead to higher latency, as context switches at operating system level generally take longer than a `kvm_exit` and `kvm_entry`.

When the CPU was dedicated to the QEMU process, on the other hand, there was a significant increase in `kvm_exit` events. This is because every context switch takes place at hypervisor level. Nevertheless, lower latency was achieved thereby, as the qemu process is no longer influenced by the CPU scheduling of the operating system.

In the process of analyzing the `kvm_exit` events, several reasons for these exits were identified. The most frequent among these were the `APIC_WRITE` and `HLT` events. The former is initiated when the guest writes to its Advanced Programmable Interrupt Controller (APIC), a component of the CPU that manages hardware interrupts. The latter occurs when the guest executes the `HLT` instruction, effectively halting the CPU until the next external interrupt is fired. Other significant but less frequent events included `EXTERNAL_INTERRUPT` and `IO_INSTRUCTION`. These events are indicative of the guest's interaction with hardware devices and its execution of I/O operations. Events such as `EPT_MISCONFIG` and `PREEMPTION_TIMER` were also noted. These could potentially signal issues with memory management and the host's scheduling of the guest. While events like `PAUSE_INSTRUCTION`, `EPT_VIOLATION`, `EOI_INDUCED`, `MSR_READ`, and `CPUID` were the least frequent, they still provide valuable insights into the guest's behavior and the host-guest interaction.

The gnuplot latency is visible in Figure 8

VARAN-Bus PCV-521

Windows

Ubuntu

WSL

In Xenomai 3, you need:

The Linux kernel with the Dovetail interface, which allows the kernel to handle real-time tasks with low latency. The Cobalt real-time core, which is responsible for scheduling and executing real-time tasks. In Xenomai 4, you need: The Linux kernel with the EVL interface, which, like Dovetail, enables the kernel to handle real-time tasks with low latency. The libe vl library, which provides a user interface to the EVL core, allowing applications to use the real-time capabilities provided by EVL. So, while both versions require a Linux kernel with a real-time interface (Dovetail for Xenomai 3, EVL for Xenomai 4), Xenomai 3 uses a real-time core (Cobalt), while Xenomai 4 uses a library (libe vl) to provide applications with access to its real-time capabilities.
